Rarebooksclub.com, United States, 2012. Paperback. Book Condition: New. 246 x 189 mm. Language: English . Brand New Book \*\*\*\*\* Print on Demand \*\*\*\*\*.This historic book may have numerous typos and missing text. Purchasers can download a free scanned copy of the original book (without typos) from the publisher. Not indexed. Not illustrated. 1914 Excerpt: .some exceptions, just these components are subject to migration in magmatic differentiation. The processes which in time past led to the formation of the basic segregations found in many plutonic rocks, the basic borders of many dykes, and the melanokratic diachist dykes of many eruptive areas, are known generally. All these products of magmatic differentiation are characterized by an increase in iron minerals, chiefly titaniferous iron, in ferro-magnesium silicates, and generally in the anorthite components of the felspars. As will be more closely discussed when describing the occurrences of titaniferous-iron ore, in many cases this enrichment of heavy minerals has proceeded so far that such segregations consist exclusively or preponderantly of one ore-mineral. Accordingly, from a genetic point of view, whenever such enrichment is pronounced, the particular aggregates are to be regarded as anchi-monomineral or perhaps even as pure monomineral eruptive rocks. Sometimes, as illustrated in Fig. 2, the segregation took place in situ; in most cases however it was only after becoming enriched that the magma was forced up, forming then differentiated lodes or streaks in the eruptive, or exceptionally in the country-rock. Such lodes or streaks are illustrated in Figs. 1, 13, 15, 16, 141, and 170. In addition to these magmatic segregations, the pneumatolytic and the contact-metamorphic deposits must also be considered, both in genesis and in space, as occurring in close relation to eruptive magmas. There is this difference however, that while the magmatic segregations result from a single process, that of...
